Overview

The XilSKey library provides APIs for programming and reading eFUSE bits and for programming the battery-backed RAM (BBRAM) of Zynq-7000 SoC, UltraScale, UltraScale+ and the Zynq UltraScale+ MPSoC devices.

- In Zynq-7000 devices:
 - PS eFUSE holds the RSA primary key hash bits and user feature bits, which can enable or disable some Zynq-7000 processor features.
 - PL eFUSE holds the AES key, the user key and some of the feature bits.
 - PL BBRAM holds the AES key.
- In Kintex/Virtex UltraScale or UltraScale+:
 - PL eFUSE holds the AES key, 32 bit and 128 bit user key, RSA hash and some of the feature bits.
 - PL BBRAM holds AES key with or without DPA protection enable or obfuscated key programming.
- In Zynq UltraScale+ MPSoC:
 - PUF registration and Regeneration.
 - 。 PS eFUSE holds:

Programming AES key and can perform CRC verification of AES key

- Programming/Reading User fuses
- Programming/Reading PPK0/PPK1 sha3 hash
- Programming/Reading SPKID
- Programming/Reading secure control bits
 - PS BBRAM holds the AES key.
 - PL eFUSE holds the AES key, 32 bit and 128 bit user key, RSA hash and some of the feature bits.
 - PL BBRAM holds AES key with or without DPA protection enable or obfuscated key programming.

BOARD Support Package Settings

There are few configurable parameters available under bsp settings, which can be configured during compilation of board support package.

The below configurations helps in adding new device information not supported by default. Currently, MicroBlaze, Zynq UltraScale and Zynq UltraScale+ MPSoC devices are supported.

Parameter Name	Description
device_id	Mention the device ID
device_irlen	Mention IR length of the device. Default is 0
device_numslr	Mention number of SLRs available. Range of values can be 1 to 4. Default is 1. If no slaves are present and only one master SLR is available then only 1 number of SLR is available.
device_series	Select the device series. Default is FPGA SERIES ZYNQ. The following device series are supported:XSK_FPGA_SERIES_ZYNQ - Select if the device belongs to the Zynq-7000 family. XSK_FPGA_SERIES_ULTRA - Select if the device belongs to the Zynq UltraScale family. XSK_FPGA_SERIES_ULTRA_PLUS - Select if the device belongs to Zynq UltraScale MPSoC family.
device_masterslr	Mention the master SLR number. Default is 0.

Parameter Name	Description
override_sysmon_cfg	Default = TRUE, library configures sysmon before accessing efuse memory. If you are using the Sysmon library and XilSkey library together, XilSkey overwrites the user defined sysmon configuration by default. When override_sysmon_cfg is set to false, XilSkey expects you to configure the sysmon to read the 3 ADC channels - Supply 1 (VPINT), Supply 3 (VPAUX) and LPD Temperature. XilSkey validates the user defined sysmon configuration is correct before performing the eFuse operations.

.. note:: On Ultrascale and Ultrascale plus devices there can be multiple or single SLRs and among which one can be master and the others are slaves, where SLR 0 is not always the master SLR. Based on master and slave SLR order SLRs in this library are referred with config order index. Master SLR is mentioned with CONFIG ORDER 0, then follows the slaves config order, CONFIG ORDER 1,2 and 3 are for slaves in order. Due to the added support for the SSIT devices, it is recommended to use the updated library with updated examples only for the UltraScale and the UltraScale+ devices.

Hardware Setup

This section describes the hardware setup required for programming PL BBRAM or PL eFUSE.

Hardware setup for Zynq PL

This section describes the hardware setup required for programming BBRAM or eFUSE of Zynq PL devices. PL eFUSE or PL BBRAM is accessed through PS via MIO pins which are used for communication PL eFUSE or PL BBRAM through JTAG signals, these can be changed depending on the hardware setup. A hardware setup which dedicates four MIO pins for JTAG signals should be used and the MIO pins should be mentioned in application header file (xilskey_input.h). There should be a method to download this example and have the MIO pins connected to JTAG before running this application. You can change the listed pins at your discretion.

MUX Usage Requirements

To write the PL eFUSE or PL BBRAM using a driver you must:

- Use four MIO lines (TCK,TMS,TDO,TDI)
- Connect the MIO lines to a JTAG port

If you want to switch between the external JTAG and JTAG operation driven by the MIOs, you must:

- Include a MUX between the external JTAG and the JTAG operation driven by the MIOs
- Assign a MUX selection PIN

To rephrase, to select JTAG for PL EFUSE or PL BBRAM writing, you must define the following:

- The MIOs used for JTAG operations (TCK,TMS,TDI,TDO).
- The MIO used for the MUX Select Line.
- The Value on the MUX Select line, to select JTAG for PL eFUSE or PL BBRAM writing.

The following graphic illustrates the correct MUX usage:

PS PLDAP TAP JTAG Port **MUX Select** MUX TCK,TMS,TDI & TDO 4 External JTAG

Figure 1: MUX Usage

Note: If you use the Vivado Device Programmer tool to burn PL eFUSEs, there is no need for MUX circuitry or MIO pins.

Hardware setup for UltraScale or UltraScale+

This section describes the hardware setup required for programming BBRAM or eFUSE of UltraScale devices. Accessing UltraScale MicroBlaze eFuse is done by using block RAM initialization. UltraScale eFUSE programming is done through MASTER JTAG. Crucial Programming sequence will be taken care by Hardware module. It is mandatory to add Hardware module in the design. Use hardware module's vhd code and instructions provided to add Hardware module in the design.

- You need to add the Master JTAG primitive to design, that is, the MASTER_JTAG_inst
 instantiation has to be performed and AXI GPIO pins have to be connected to TDO, TDI, TMS
 and TCK signals of the MASTER_JTAG primitive.
- For programming eFUSE, along with master JTAG, hardware module(HWM) has to be added
 in design and it's signals XSK_EFUSEPL_AXI_GPIO_HWM_READY,
 XSK_EFUSEPL_AXI_GPIO_HWM_END and XSK_EFUSEPL_AXI_GPIO_HWM_START, needs
 to be connected to AXI GPIO pins to communicate with HWM. Hardware module is not
 mandatory for programming BBRAM. If your design has a HWM, it is not harmful for
 accessing BBRAM.
- All inputs (Master JTAG's TDO and HWM's HWM_READY, HWM_END) and all outputs (Master JTAG TDI, TMS, TCK and HWM's HWM_START) can be connected in one channel (or) inputs in one channel and outputs in other channel.
- Some of the outputs of GPIO in one channel and some others in different channels are not supported.
- The design should contain AXI BRAM control memory mapped (1MB).

Note: MASTER JTAG will disable all other JTAGs.

For providing inputs of MASTER JTAG signals and HWM signals connected to the GPIO pins and GPIO channels, refer GPIO Pins Used for PL Master JTAG Signal and GPIO Channels sections of the UltraScale User-Configurable PL eFUSE Parameters and UltraScale User-Configurable PL BBRAM Parameters. The procedure for programming BBRAM of eFUSE of UltraScale or UltraScale+ can be referred at UltraScale BBRAM Access Procedure and UltraScale eFUSE Access Procedure.

Source Files

The following is a list of eFUSE and BBRAM application project files, folders and macros.

- xilskey_efuse_example.c: This file contains the main application code. The file helps in the PS/PL structure initialization and writes/reads the PS/PL eFUSE based on the user settings provided in the xilskey_input.h file.
- xilskey_input.h: This file ontains all the actions that are supported by the eFUSE library. Using
 the preprocessor directives given in the file, you can read/write the bits in the PS/PL eFUSE.
 More explanation of each directive is provided in the following sections. Burning or reading
 the PS/PL eFUSE bits is based on the values set in the xilskey_input.h file. Also contains GPIO
 pins and channels connected to MASTER JTAG primitive and hardware module to access
 Ultrascale eFUSE.

In this file:

- specify the 256 bit key to be programmed into BBRAM.
- specify the AES(256 bit) key, User (32 bit and 128 bit) keys and RSA key hash(384 bit) key to be programmed into UltraScale eFUSE.

- XSK_EFUSEPS_DRIVER: Define to enable the writing and reading of PS eFUSE.
- XSK_EFUSEPL_DRIVER: Define to enable the writing of PL eFUSE.
- xilskey_bbram_example.c: This file contains the example to program a key into BBRAM and verify the key.

Note: This algorithm only works when programming and verifying key are both executed in the recommended order.

- xilskey_efuseps_zynqmp_example.c: This file contains the example code to program the PS eFUSE and read back of eFUSE bits from the cache.
- xilskey_efuseps_zynqmp_input.h: This file contains all the inputs supported for eFUSE PS of Zynq UltraScale+ MPSoC. eFUSE bits are programmed based on the inputs from the xilskey_efuseps_zynqmp_input.h file.
- xilskey_bbramps_zynqmp_example.c: This file contains the example code to program and verify BBRAM key of Zynq UltraScale+ MPSoC. Default is zero. You can modify this key on top of the file.
- xilskey_bbram_ultrascale_example.c: This file contains example code to program and verify BBRAM key of UltraScale.

Note: Programming and verification of BBRAM key cannot be done separately.

- xilskey_bbram_ultrascale_input.h: This file contains all the preprocessor directives you need to provide. In this file, specify BBRAM AES key or Obfuscated AES key to be programmed, DPA protection enable and, GPIO pins and channels connected to MASTER JTAG primitive.
- xilskey_puf_registration.c: This file contains all the PUF related code. This example illustrates
 PUF registration and generating black key and programming eFUSE with PUF helper data,
 CHash and Auxilary data along with the Black key.
- xilskey_puf_registration.h: This file contains all the preprocessor directives based on which read/write the eFUSE bits and Syndrome data generation. More explanation of each directive is provided in the following sections.

CAUTION! Ensure that you enter the correct information before writing or 'burning' eFUSE bits. Once burned, they cannot be changed. The BBRAM key can be programmed any number of times.

Note: POR reset is required for the eFUSE values to be recognized.

eFUSE PL API

This chapter provides a linked summary and detailed descriptions of the eFUSE APIs of Zynq eFUSE PL and UltraScale eFUSE.

Example Usage

- The Zynq eFUSE PL and UltraScale example application should contain the xilskey_efuse_example.c and the xilskey_input.h files.
- By default, both the eFUSE PS and PL are enabled in the application. You can comment 'XSK_EFUSEPL_DRIVER' to execute only the PS.
- For UltraScale, it is mandatory to comment `XSK_EFUSEPS_DRIVER else the example will generate an error.
- For more details on the user configurable parameters, refer Zynq User-Configurable PL eFUSE Parameters and UltraScale or UltraScale+ User-Configurable PL eFUSE Parameters.
- Requires hardware setup to program PL eFUSE of Zynq or UltraScale.

Note: Contains the function prototypes, defines and macros for the PL eFUSE functionality.

u32	XilSkey_CrcCalculation_AesKey	const u8 * Key

Functions

XilSKey_CrcCalculation

This function Calculates CRC value based on hexadecimal string passed.

Note: If the length of the string provided is less than 64, this function appends the string with zeros. For calculation of AES key's CRC one can use u32 XilSKey_CrcCalculation(u8 *Key) API or reverse polynomial 0x82F63B78.

Parameters

The following table lists the XilSKey_CrcCalculation function arguments.

Table 41: XilSKey_CrcCalculation Arguments

Туре	Name	Description
const u8 *		Pointer to the string contains AES key in hexadecimal of length less than or equal to 64.

Returns

- On Success returns the Crc of AES key value.

User-Configurable Parameters

This section provides detailed descriptions of the various user configurable parameters.

Zynq User-Configurable PS eFUSE Parameters

Define the XSK_EFUSEPS_DRIVER macro to use the PS eFUSE.

After defining the macro, provide the inputs defined with XSK_EFUSEPS_DRIVER to burn the bits in PS eFUSE. If the bit is to be burned, define the macro as TRUE; otherwise define the macro as FALSE. For details, refer the following table.

Macro Name	Description
XSK_EFUSEPS_ENABLE_WRITE_PROTECT	Default = FALSE.
	TRUE to burn the write-protect bits in eFUSE array. Write protect has two bits. When either of the bits is burned, it is considered write-protected. So, while burning the write-protected bits, even if one bit is blown, write API returns success. As previously mentioned, POR reset is required after burning for write protection of the eFUSE bits to go into effect. It is recommended to do the POR reset after write protection. Also note that, after write-protect bits are burned, no more eFUSE writes are possible.
	If the write-protect macro is TRUE with other macros, write protect is burned in the last iteration, after burning all the defined values, so that for any error while burning other macros will not effect the total eFUSE array.
	FALSE does not modify the write-protect bits.
XSK_EFUSEPS_ENABLE_RSA_AUTH	Default = FALSE.
	Use TRUE to burn the RSA enable bit in the PS eFUSE array. After enabling the bit, every successive boot must be RSA-enabled apart from JTAG. Before burning (blowing) this bit, make sure that eFUSE array has the valid PPK hash. If the PPK hash burning is enabled, only after writing the hash successfully, RSA enable bit will be blown. For the RSA enable bit to take effect, POR reset is required. FALSE does not modify the RSA enable bit.
XSK_EFUSEPS_ENABLE_ROM_128K_CRC	Default = FALSE.
	TRUE burns the ROM 128K CRC bit. In every successive boot, BootROM calculates 128k CRC. FALSE does not modify the ROM CRC 128K bit.

Macro Name	Description

	KEY_128BIT and XSK_EFUSEPL_PGM_SLR_CONFIG_
	ORDER_3 are enabled with TRUE value.

CAUTION! If you want to program USER key for SLR 1 and AES key for SLR2 then this should be done separately. For this you need to enable the XSK_EFUSEPL_PGM_SLR1, XSK_EFUSEPL_PGM_SLR2, XSK_EFUSEPL_PROGRAM_USER_KEY, and XSK_EFUSEPL_PROGRAM_AES_KEY parameters with the TRUE value. If you do all the settings in one single go and provide the USER key in XSK_EFUSEPL_USER_KEY and AES key in XSK_EFUSEPL_AES_KEY_SLR2 then:

Enabling XSK_EFUSEPL_PROGRAM_USER_KEY will enable programming of USER key for both SLR1 And SLR2 as programming is enabled for both the SLR.

- Enabling XSK_EFUSEPL_PROGRAM_AES_KEY will enable programming of AES key for both SLR1 And SLR2 as programming is enabled for both the SLR.
- If you want to program USER key only for SLR1, then provided USER key will be programmed for SLR1 and Default key (all zeroes) will be programmed for SLR2.
- If you want to program AES key only for SLR2, then provided AES key will be programmed for SLR2 and Default key will be programmed for SLR1.

To avoid all the above mentioned scenarios, if programming is required for different key on different SLR, separate runs should be done.

Error Codes

The application error code is 32 bits long.

For example, if the error code for PS is 0x8A05:

- 0x8A indicates that a write error has occurred while writing RSA Authentication bit.
- 0x05 indicates that write error is due to the write temperature out of range.

Applications have the following options on how to show error status. Both of these methods of conveying the status are implemented by default. However, UART is required to be present and initialized for status to be displayed through UART.

- Send the error code through UART pins
- Write the error code in the reboot status register

Status Codes

For Zynq and UltraScale, the status in the xilskey_efuse_example.c file is conveyed through a UART or reboot status register in the following format: 0xYYYYZZZZ, where:

- YYYY represents the PS eFUSE Status.
- ZZZZ represents the PL eFUSE Status.

The table below lists the status codes.

For Zynq UltraScale+ MPSoC, the status in the xilskey_bbramps_zynqmp_example.c, xilskey_puf_registration.c and xilskey_efuseps_zynqmp_example.c files is conveyed as 32 bit error code. Where Zero represents that no error has occurred and if the value is other than Zero, a 32 bit error code is returned.

Status Code Values	Description
0x0000ZZZZ	Represents PS eFUSE is successful and PL eFUSE process returned with error.
0xYYYY0000	Represents PL eFUSE is successful and PS eFUSE process returned with error.
0xFFFF0000	Represents PS eFUSE is not initiated and PL eFUSE is successful.
0x0000FFFF	Represents PL eFUSE is not initiated and PS eFUSE is successful.
0xFFFFZZZZ	Represents PS eFUSE is not initiated and PL eFUSE is process returned with error.
0xYYYYFFFF	Represents PL eFUSE is not initiated and PS eFUSE is process returned with error.

Procedures

This section provides detailed descriptions of the various procedures.

Zynq eFUSE Writing Procedure Running from DDR as an Application

This sequence is same as the existing flow described below.

- 1. Provide the required inputs in xilskey_input.h, then compile the platform project.
- 2. Take the latest FSBL (ELF), stitch the <output>.elf generated to it (using the bootgen utility), and generate a bootable image.
- 3. Write the generated binary image into the flash device (for example: QSPI, NAND).
- 4. To burn the eFUSE key bits, execute the image.

Zynq eFUSE Driver Compilation Procedure for OCM

The procedure is as follows:

- 1. Open the linker script (lscript.ld) in the platform project.
- 2. Map all the sections to point to ps7_ram_0_S_AXI_BASEADDR instead of ps7_ddr_0_S_AXI_BASEADDR. For example, Click the Memory Region tab for the .text section and select ps7_ram_0_S_AXI_BASEADDR from the drop-down list.
- 3. Copy the ps7_init.c and ps7_init.h files from the hw_platform folder into the example folder.
- 4. In xilskey_efuse_example.c, un-comment the code that calls the ps7_init() routine.
- 5. Compile the project.

The <Project name >. elf file is generated and is executed out of OCM.

When executed, this example displays the success/failure of the eFUSE application in a display message via UART (if UART is present and initialized) or the reboot status register.

UltraScale eFUSE Access Procedure

The procedure is as follows:

- 1. After providing the required inputs in xilskey_input.h, compile the project.
- 2. Generate a memory mapped interface file using TCL command write_mem_info
- 3. Update memory has to be done using the tcl command updatemem.
- 4. Program the board using \$Final.bit bitstream.
- 5. Output can be seen in UART terminal.

UltraScale BBRAM Access Procedure

The procedure is as follows:

- 1. After providing the required inputs in the xilskey_bbram_ultrascale_input.h` file, compile the project.
- 2. Generate a memory mapped interface file using TCL command
- 3. Update memory has to be done using the tcl command updatemem:
- 4. Program the board using \$Final.bit bitstream.
- 5. Output can be seen in UART terminal.

Data Structure Index

The following is a list of data structures:

XilSKey_EPI

XilSKey_EPI
